

Traffic Theory &amp; queueing system

Question Number etc. in left margin

Mark allocation in right margin

Q1a)  $N > M$ : no congestion will occur,  $i_{\max} = M$ 

$$\pi_i = \left( \frac{\lambda i - 1}{\mu i} \right) \pi_{i-1} = \left( \frac{(M - (i-1))\lambda}{i\mu} \right) \pi_{i-1}$$

Recursively:

$$\pi_i = \binom{M}{i} \alpha^i \pi_0 \quad i=1, 2, \dots, M \quad \text{and} \quad \alpha = \lambda/\mu$$

$$\pi_0 = \left[ \sum_{j=0}^M \binom{M}{j} \alpha^j \right]^{-1}$$

$$\text{let } p = \frac{\alpha}{1+\alpha} \iff \alpha = \frac{p}{1-p}$$

multiplying numerator and denominator of  $\pi_i$  by the factor  $(1-p)^M$  we get:

$$\pi_i = \frac{\binom{M}{i} p^i (1-p)^{M-i}}{\sum_{j=0}^M \binom{M}{j} p^j (1-p)^{M-j}} \quad i=0, 1, \dots, M$$

 $(\pi_i)$  is binomial  $(M, p)$ 

Q1b)

$$\pi_2 = \binom{3}{2} \left( \frac{1}{2} \right)^2 \left( \frac{1}{2} \right)^1 = \frac{3!}{2!(3-2)!} \left( \frac{1}{2} \right)^3$$

$$= 0.375$$

$$p = \frac{\lambda}{\mu + \lambda}$$

Question Number etc. in left margin

Mark allocation in right margin

Q2a)  $M/M/K$  recursive expression

$$\pi_i = \begin{cases} (A^i/i!) \pi_0 & i \leq K \\ (A^K/K!) \rho^{i-K} \pi_0 & i \geq K \end{cases} \quad \begin{aligned} A &= \lambda/\mu \\ \rho &= A/K \end{aligned}$$

Also for  $i \geq K$ ,  $i = K+j$  ( $j \geq 0$ ) and then

$$\pi_{K+j} = \left(\frac{A^K}{K!}\right) \rho^j \pi_0 = \rho^j \pi_K \quad ; \quad \pi_K = \left(\frac{A^K}{K!}\right) \pi_0$$

$$\pi_0 = \frac{1}{(A^K/K!)} \left[ \frac{(1-\rho) E_K(A)}{(1-\rho) + \rho E_K(A)} \right] \quad E_K(A) = \frac{A^K/K!}{\sum_{i=0}^{\infty} A^i/i!}$$

$$P(\text{delay}) = P(W > 0) = P(N_t \geq K)$$

$$P(N_t \geq K) = \sum_{i=K}^{\infty} \pi_i = \sum_{j=0}^{\infty} \pi_{K+j} = \sum_{j=0}^{\infty} \pi_K \rho^j$$

$$= \frac{\pi_K}{1-\rho} = \frac{(A^K/K!) \pi_0}{1-\rho} = \frac{E_K(A)}{(1-\rho) + \rho E_K(A)} = D_A$$

Q2b) For delay arrivals

$$\begin{aligned} P(W > z | Q_t = i) &= P(<(i+1) \text{ departures in } (0, z)) \\ &= \sum_{j=0}^i \frac{(K\mu z)^j}{j!} e^{-K\mu z} \end{aligned}$$

in equilibrium, we know for delay arrivals

$$P(Q_t = i) = (1-\rho) \rho^i$$

Therefore

$$\begin{aligned} P(W > z) &= \sum_{i=0}^{\infty} P(Q_t = i) P(W > z | Q_t = i) \\ &= \sum_{i=0}^{\infty} (1-\rho) \rho^i \sum_{j=0}^i \frac{(K\mu z)^j}{j!} e^{-K\mu z} \\ &= e^{-K\mu (1-\rho) z} \end{aligned}$$

(the interchange summation order and using  $\lambda = K\mu\rho$ )

Question Number etc. in left margin

Mark allocation in right margin

Q3a i) Equivalent capacity and admission control

How much traffic can a VP can handle if a prescribed QoS for each traffic class is to be maintained. For example given the capacity of a VP. How many VC can it handle. Or, given a number of active VC, can we admit one more.

- Assume on-OFF traffic sources: peak rate  $R_p$ , average burst length  $1/\mu$  and average silence length  $1/\kappa$
- single class admission control

- a) large number of sources multiplexed (ignore effect of buffer). A binomial distribution is approximated quite closely by a normal distribution.
- b) If the effect of the access buffer is considered a fluid flow approximation is obtained.

$$\text{Eq Capacity} = \min[Sb(a), Sb(b)]$$

- ii) Leaky Bucket is one possible algorithm to control the traffic during the period of a connection. User send violate their connection agreement may have cells dropped or traffic may be shaped or smoothed to reduce any adverse impact on the network. This is a form of open loop access control.

An interpretation of the leaky bucket algorithm involves the use of a "token pool" buffer. A cell must have a token waiting to be transmitted.

Tokens are generated one per D sec, and wait in the buffer, until buffer fills. At this time no further token is generated. Note,

that as expected in this case the average throughput drops from the input load (provided cell loss) 5

Question Number etc. in left margin

Mark allocation in right margin

Q3b) The system is M/G/1

$$\text{mean packet length} = \frac{1}{4} 160 + \frac{1}{4} 80 + \frac{1}{2} 320 = 220 = \frac{11}{4} 80$$

$$\begin{aligned} \text{mean square packet length} &= \frac{1}{4} (160)^2 + \frac{1}{4} (80)^2 + \frac{1}{2} (320)^2 \\ &= 59200 = \left( \frac{4+1+16 \cdot 2}{4} \right) (80)^2 = \frac{37}{4} 80^2 \end{aligned}$$

hence:

$$E(s) = \frac{11}{4} \frac{80}{64} \times 10^{-3} = 3.4375 \text{ (ms)}$$

$$E(s^2) = \frac{37}{4} \frac{(80)^2}{(64)^2} \times (10^{-3})^2 = 14.45 \text{ (ms}^2\text{)}$$

$$\rho = \lambda E(s) = 200 \times 3.4375 \times 10^{-3} = 0.687$$

using Pollaczek-Khinchin formula

$$E(w) = \left[ \frac{\lambda E(s^2)}{2(1-\rho)} \right] = \frac{200 \times 14.45 \times 10^{-6}}{2(1-0.687)} = 4.61 \text{ ms}$$

$$\begin{aligned} E(T) &= E(w) + E(s) = (4.61 + 3.43) \text{ ms} \\ &= 8 \text{ ms} \end{aligned}$$

$$E(w) = \frac{E(r)}{1-\rho}$$

$$E(r) = \frac{1}{2} \lambda E[s^2]$$

Question Number etc. in left margin

Mark allocation in right margin

Q4a

M/G/1 system

$$E[W] = \frac{E[R]}{1-\rho}$$

$$E[R] = \frac{1}{2} \lambda E[s^2]$$

$$E[W] = \frac{\lambda E[s^2]}{2(1-\rho)}$$

Applying Little

$$E[Q_t] = \frac{\lambda^2 E[s^2]}{2(1-\rho)}$$

5

5

Q4b

For pure chance traffic with  $\rho=13$  and  $N=20$ 

$$B_c = E_{20}(13) = 0.02 \text{ (from chart)}$$

i) mean carried traffic

$$\rho_c = (1-B_c) \rho = 12.74 \text{ erlangs}$$

2

ii) mean channel occupancy is

$$\eta = \frac{\rho_c}{N} = \frac{12.74}{20} = 0.637$$

2

iii) for  $N=\infty$ 

$$\pi_i = \frac{\rho^i}{i!} e^{-\rho} \quad i=0,1,2,\dots$$

Proportion that at most 2 circuits are occupied =

$$\pi_0 + \pi_1 + \pi_2 = e^{-\rho} + \rho e^{-\rho} + \frac{\rho^2}{2} e^{-\rho}$$

6

$$= 2.26 \times 10^{-4}$$

Question Number etc. in left margin

Mark allocation in right margin

Q5a) For a non pre-emptive priority system

$$E[W_1] = \frac{E[R]}{1-\rho_1}, \quad E[W_2] = \frac{E[R]}{(1-\rho_1)(1-\rho_1-\rho_2)}$$

$$E[R] = \frac{1}{2} \lambda E[S^2]$$

$$= \frac{1}{2} \lambda \left[ \left( \frac{\lambda_1}{\lambda} \right) E(S_1^2) + \left( \frac{\lambda_2}{\lambda} \right) E(S_2^2) + \left( \frac{\lambda_3}{\lambda} \right) E(S_3^2) \right]$$

$$= \frac{1}{2} \left( \lambda_1 E(S_1^2) + \lambda_2 E(S_2^2) + \lambda_3 E(S_3^2) \right)$$

$$\rho_k = \lambda_k E[S_k] \quad \rho_1 = .4, \quad \rho_2 = .3, \quad \rho = .1$$

$$E[R] = \frac{1}{2} [2 \cdot 3 + 3 \cdot 5 + 1 \cdot 1] = 11$$

$$E[W_1] = \frac{11}{1-0.4}$$

$$= 18.33$$

$$E[W_2] = \frac{11}{(1-0.4)(1-0.4-0.3)}$$

$$= 61.1$$

5

Question Number etc. in left margin

Mark allocation in right margin

$$\text{iii) } \mu_p \left( \frac{d}{x+n} \right) < D$$

$\rho_p \left( \frac{\lambda}{\lambda + \mu} \right) \sim \text{average cells/s entering the queue}$

$$\Rightarrow \rho = \frac{\mu \left( \frac{\lambda}{\alpha + \lambda} \right)}{\beta} < 1$$

2

3

5

Question Number etc. in left margin

Mark allocation in right margin

(6a)

- one voice source will generate cells at a rate  $v$  [cells/s] during a talk spurt of average length  $\frac{1}{\alpha}$  [s].

$\Rightarrow x$  (unit of information) is transmitted by  $\frac{v}{\alpha}$  cells during a talk spurt

- If the system capacity is  $vc$  [cells/s]

$\Rightarrow$  equivalent capacity  $\frac{vc}{\frac{v}{\alpha}} = \alpha c$

ii)  $i$  source on  $\Rightarrow i v$  [cells/s]  $\Rightarrow \frac{i v}{\frac{v}{\alpha}} = \alpha i$

$$\frac{\Delta x}{\Delta t} = (i - c) \alpha$$

$i > c$  for the buffer to be filled

(6b)

i) state space  $\textcircled{I}$  = syst fully operational

$\textcircled{Hw}$  = hw failure

$\textcircled{Sw}$  = sw failure

ii)

$$356[d] \times 24[h] \times 60[m] \times 60[s]$$

$$\lambda \cdot 3.17 \times 10^{-8} [1/s]$$

Rates need to be given in same scale
